Introduction

LTE is the standard defined to communicate with cell phones in a wide area network, while Wi-Fi is the standard designed for local area networks, and we use both daily. Both are deployed in mines for different applications, and physics defines the limitations of each. LTE uses lower frequencies to cover a more extended range but with lower throughput, while Wi-Fi uses higher frequencies to obtain higher throughput at shorter distances. Rajant integrates both technologies into its radios and has enabled machine-to-machine communication since the company's creation in 2001 to extend the range and throughput past the limitations of fixed infrastructure.

In this document, we test Rajant's latest LTE radio integration with Rajant Kinetic Mesh® at different mining locations to demonstrate seamless roaming between Rajant Kinetic Mesh and LTE, along with documenting actual throughput and latency achieved. Conducted tests were run over private and public LTE networks. This document, however, primarily covers the Rajant testing over private LTE networks as public networks are less prevalent in mining, and test results showed a lot of variabilities, so maintaining consistent backhaul throughput was not possible.

In this document, one of the available networks supported a channel bandwidth of 10Mhz of LTE RF spectrum, resulting in a 20Mbps download speed and 10Mbps upload speed. An additional private network was provided at another site with 5Mhz of LTE Spectrum with a 10Mbps download speed and less than 5Mbps upload speed.

During the testing, Rajant achieved 99.5Mbps throughput over Kinetic Mesh with 1.786ms latency and 19.1 Mbps throughput over private LTE with 38.701ms latency.

Utilization of Rajant's Remote Protocol Tunneling (RPT) is required to mesh over a Layer3 LTE connection.

Note: The goal of implementing an RPT connection over Public LTE was to determine what was required to avoid Carrier Grade Network Address Translation to establish Remote Protocol Tunnels over the infrastructure routes with some connectivity over a public network. Throughput testing revealed an excessive variance in latency and cost. Public LTE networks for reliable and required application throughput should be avoided as public LTE saw latencies between 125-133 msec with route costs greater than 28,000.

The purpose of the testing was:

- » Integrate with the private LTE network at multiple mine sites
- » Confirm SIM card validation on the private mine site and the public LTE networks
- » Establish Remote Protocol Tunnels and confirmation of functionality
- » Confirm latency over the RPT link
- » Confirm RPT could route traffic when it was the best path cost
- » Confirm mesh links could route traffic when mesh link cost bettered RPT costs
- » Integrate with public LTE and determine best practice to deal with CGNAT

Rajant equipment deployed over the mine:

- » Peregrine FE1-2255B
- » Peregrine 2455LW with LTE interface running 11.25.1 firmware
- » Slipstream 2 running 11.25.1 firmware

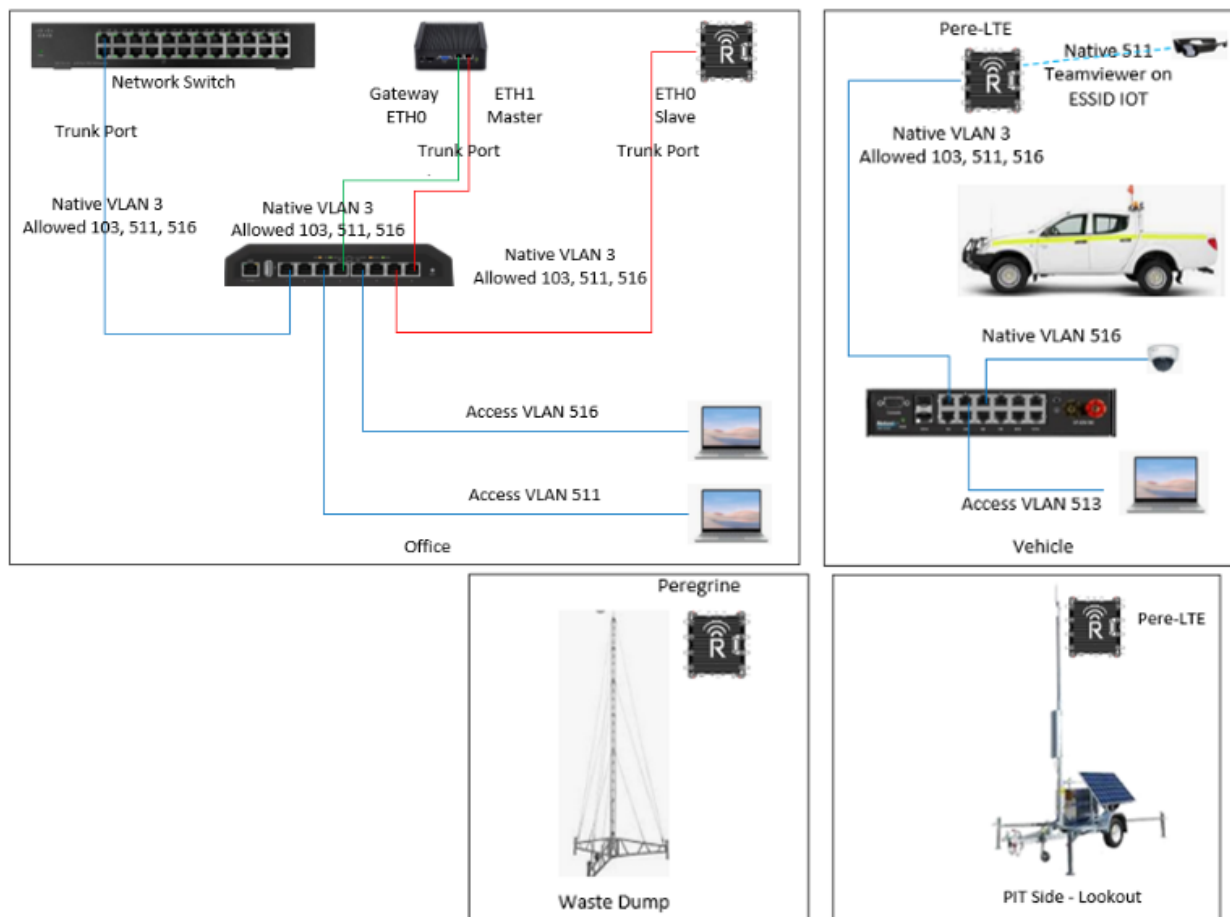

Establish Remote Protocol Tunnels and Confirm Functionality

Remote Protocol Tunnelling was established over UDP. To enable the remote protocol tunnel to function, the following node configurations were applied.

SlipStream RPT Configuration

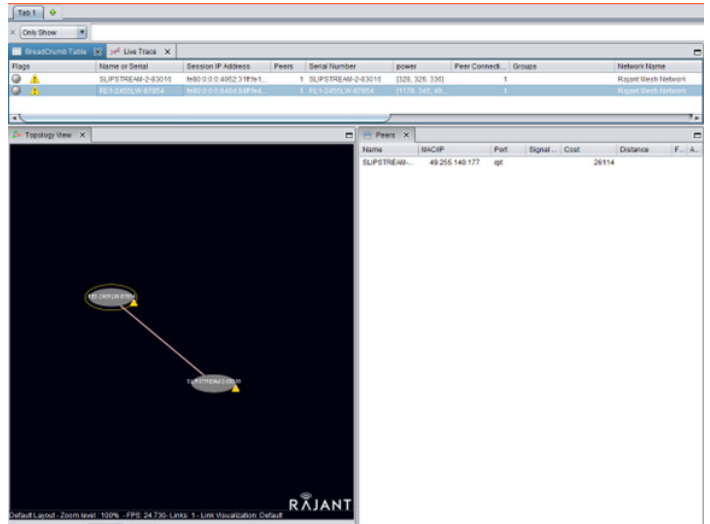

SlipStream connected via Eth0 to the network switch. The SlipStream network was configured with a static IP address based on its computed V11 address. The SlipStream ETH0 port was configured in gateway mode – with gateway IP address details established via DHCP. ETH 1 was connected to the network switch port.

The figure below shows a block diagram of the mine site test network configuration.

The following was applied on the SlipStream in InstaMesh® (No changes were enabled on the advanced InstaMesh tab). RPT configs are necessary as the Rajant BreadCrumbs® need Remote Protocol Tunneling in order to mesh over LTE. InstaMesh on the Peregrines were configured for RPT using the DHCP assigned gateway IP as the RPT tunnelling address.

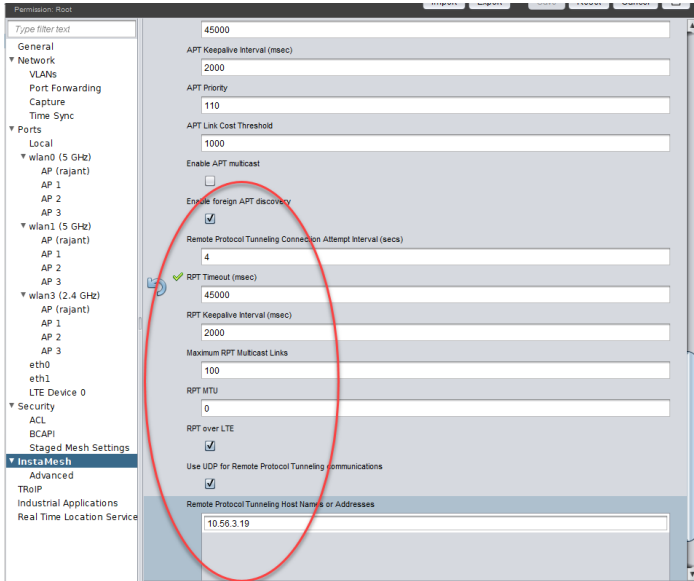

This image shows RPT tunnels established over LTE between each node and the SlipStream.

LTE Coverage Depiction

Green circles represent Rajant preferred over LTE. Higher bandwidth and lower latency – shows pit-side node meshing with admin node. Blue circles represent LTE coverage.

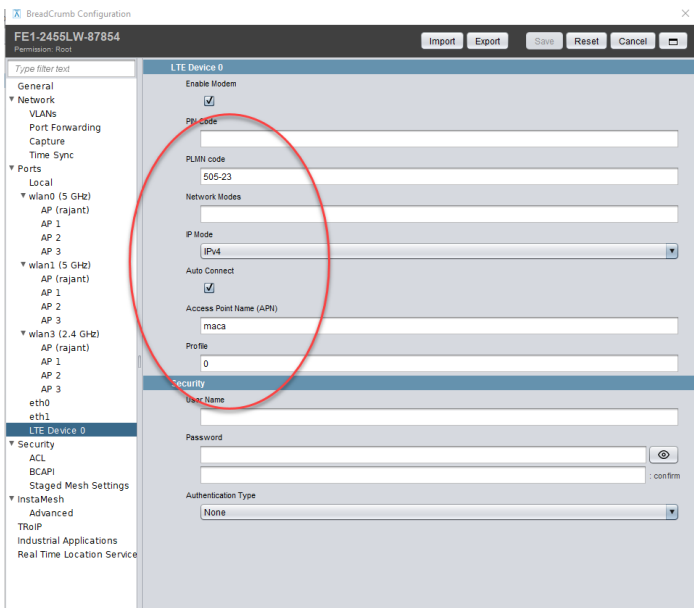

NOTE - During the trial, we deliberately ensured the pit-side node could NOT mesh with the admin node so we would use the LTE backhaul.

Node Configurations on Peregrine LTE

Network address was established as per the SlipStream - Manually assigned based on computed V11, but in a /24 subnet.

The LTE interface was enabled with the following credentials applied:

In the image below, the LTE tower is on the left. The admin node is mounted to the roof of the building on the right. The pit-side node is behind the dirt pile directly ahead of the vehicle. The pit-side node was in an LTE coverage area, so it could mesh from the admin building to the pit-side node to switch to LTE. **In a real world deployment , we would have allowed the pit-side node to mesh with the admin node as that provides a 5-6x increase in throughput.**

Test Results

Standard Rajant BreadCrumb nodes (non-LTE) are also able to use the 4G/LTE connections of the hybrid Rajant nodes via the wireless Kinetic Mesh when LTE has the best cost.

The Rajant hybrid BreadCrumbs could seamlessly switch between wireless Kinetic Mesh and 4G/LTE connections. Peer routes are switched without dropping packets.

Trace Path Cost: 602

LINK COUNT PER WLAN				
WLAN	Great Links	Good Links	Poor Links	Total Links
wlan1	1	0	0	1
wlan0	1	0	0	1
wlan3	1	0	0	1

- A great link is a link with both cost and SNR in the great range.
- A good link is a link with both cost and SNR at least in the good range, but was not a great link.
- A poor link is a link with either cost or SNR in the poor range.

WLAN0				
Serial	Name	IPv4	Peer Cost	Peer SNR
FE1-2455LW-87854		10.56.3.243	487	41

WLAN1				
Serial	Name	IPv4	Peer Cost	Peer SNR
FE1-2455LW-87854		10.56.3.243	1,201	31

WLAN3				
Serial	Name	IPv4	Peer Cost	Peer SNR
FE1-2455LW-87854		10.56.3.243	596	42

NOTE:

Using MeshMapper, we can track the progress of the mobile node within the Kinetic Mesh Infrastructure and then switch to LTE. As shown in this picture, the mobile node was in full mesh coverage as noted by excellent peer costs on all three WLANs.

100MBPS UDP throughput over the Kinetic Mesh is shown here.

In this InstaMesh trace during the testing, we can see the vehicle node offloading via Kinetic Mesh to the pit-side node and then using LTE to get from the pit-side node to the LTE tower. The solid lines depict the path for data.

Once the vehicle drives out of Kinetic Mesh coverage, LTE takes over. Data still flows without Kinetic Mesh coverage seamlessly over LTE.

Requirements to Utilize Public LTE

- » LTE providers typically implement Network Address Translation (NAT) on post-paid and pre-paid 4G/LTE SIM cards
- » The FE1-2455LW will still get an IP address for the SIM card, however this NAT prevents the RPT tunnel from being established.

For successful implementation of RPT over public LTE, *ensure APN supports a dynamic public IP address without NAT.*

Below is an example of public LTE dynamic IP Address using NAT. Note, no port bonding and no connectivity with NATing, Public LTE cannot work.

```
2069:instaMesh.cpp:1228:Failed to send keepalive to port 9, tap0rptudp9, 49.255.140.177 with error 89, Destination address required
2069:instaMesh.cpp:974:Failed to send periodic keepalive to rpt link 9, tap0rptudp9, 49.255.140.177,aptIsReady=0, handshakeDone=0
2069:instaMesh.cpp:1027:sendRptKeepAlives deleting port 9, tap0rptudp9, 49.255.140.177
2069:packet.cpp:439:Deleting port 9, tap0rptudp9, 49.255.140.177
2069:instaMesh.cpp:1228:Failed to send keepalive to port 10, tap0rptudp10, 49.255.140.177 with error 89, Destination address required
```

Below is an example of public LTE dynamic IP address without NAT. Note, port Bonding process completed.

Testing Summary

Industrial applications, like mines, require more than LTE and Wi-Fi alone. Both are deployed for different applications, and physics defines the limitations of each. When deploying a Rajant Kinetic Mesh utilizing the FE1-2455LW, with Rajant's InstaMesh protocol routing over LTE, one can see that robust connectivity remains seamless when switching between Rajant Kinetic Mesh and LTE. Kinetic Mesh achieves much lower latency and much higher throughput while leveraging a mines LTE investment.

Rajant Peregrine LTE BreadCrumb

The Peregrine LTE is interoperable with all Rajant BreadCrumb nodes. It is part of Rajant's initiative to develop deeply integrated solutions that securely combine data from connected people, vehicles, machines, and sensors, with machine learning (ML). This new high-performance industrial-grade BreadCrumb platform provides secure connections to back-end networks using Rajant's APT and RPT tunneling while actively using multiple frequencies to avoid interference and network congestion.

The Peregrine LTE uses real-time, automated packet routing to always select the best path for each packet. This data combination unlocks the benefits of process optimization, digital twins, predictive analytics, AR, VR, and more, while improving worker safety. Capable of providing a reliable connection in highly obstructed, cluttered, or shadowed areas, the Peregrine LTE is ideal to expand market capabilities for industries like rail, shipping ports, military, mining, and heavy construction.

Learn more about the award-winning Rajant Peregrine LTE BreadCrumb for the continuous, fully mobile connectivity required to power today's data-driven operations. Visit www.rajant.com or contact a representative to get started today.
